

Integral Valued Numerical Data: Measure of Central Tendency

Dhritikesh Chakrabarty

Independent Researcher, Ex Associate Professor of Statistics, Handique Girls' College, Assam, India

Abstract - In the situation where the data set to be studied consists of integral valued numerical observations, the existing measures of central tendency may fail to provide the value, which is a valid one, of central tendency since the values provided by them are not bound to be integers. A valid measure of the same, in the case of such data, has been derived in this study. This article describes the derivation of the measure and its application in the data on number of rainy days at New Delhi.

| | |
|-------|--|
| HM | Harmonic Mean |
| MoCT | Measure of Central Tendency |
| MMoCT | Mathematical Measure of Central Tendency |
| NoRD | Number of Rainy Days |

Average is a characteristic of a list of numbers/numerical values while central tendency [19, 20, 25] is that of data on a variable.

Measure of central tendency [26] is based on measure of average [3, 4, 5, 6, 7, 8, 10, 18].

The three common MMoCT of numerical data are AM, GM and HM, which are also known as Pythagorean Means [2].

Recently, some more MMoCT of data have been developed which are respectively AGM [1, 9, 14, 17, 20], AHM [10, 11, 14, 15, 16, 17, 20, 21], GHM [12, 14, 17, 20, 24] and AGHM [13, 14, 17, 20]. However, data to be studied may be of different types. There are many cases where numerical data to be studied are of integral valued so that their central value is also an integral value. In such situation, the above measures fail to provide the central value, which is a valid one, of central tendency since the values provided by them are not bound to be integers. One MoCT has therefore been developed, in this study, which is valid in such situation. This article describes the derivation of the measure and its application in the data on number of rainy days at New Delhi.

1. INTRODUCTION

The following abbreviations have been used in this article:

Table - 1

| Abbreviation | Meaning |
|--------------|------------------------------------|
| AM | Arithmetic Mean |
| AGM | Arithmetic-Geometric Mean |
| AGHM | Arithmetic-Geometric-Harmonic Mean |
| AHM | Arithmetic- Harmonic Mean |
| ANoRD | Annual Number of Rainy Days |
| CT | Central Tendency |
| GHM | Geometric-Harmonic Mean |
| GM | Geometric Mean |

2. DERIVATION OF THE MEASURE

Let

x_1, x_2, \dots, x_N

be N observations which are integral values observed on an integral valued random variable X , whose central value (central tendency) is μ .

Then each observation x_i is composed of two components; one is μ and the other is ε_i (say).

This means, the observations follow the mathematical model

$$x_i = \mu + \varepsilon_i, (i = 1, 2, \dots, N) \quad (1)$$

where

$\varepsilon_1, \varepsilon_2, \dots, \varepsilon_N$

are the respective error components of the N observations which assume positive integral values and negative integral values in $(-\infty, \infty)$ in random order.

Also,

$P(\varepsilon_i \text{ assumes positive value}) = P(\varepsilon_i \text{ assumes negative value})$

which means,

$$P(\varepsilon_i = n) = P(\varepsilon_i = -n), n \text{ is integer} \quad (2)$$

Thus,

$$\begin{aligned} E(\varepsilon_i) &= \sum_{n=-\infty}^{\infty} n P(\varepsilon_i = n) \\ &= \sum_{n=-\infty}^{-1} n P(\varepsilon_i = n) + 0 P(\varepsilon_i \\ &\quad = 0) + \sum_{n=1}^{\infty} n P(\varepsilon_i = n) \\ &= \sum_{n=1}^{\infty} (-n) P(\varepsilon_i = -n) \\ &\quad + \sum_{n=1}^{\infty} n P(\varepsilon_i = n) \\ &= \sum_{n=1}^{\infty} (-n + n) P(\varepsilon_i = n), \text{ since } P(\varepsilon_i = \\ &\quad n) = P(\varepsilon_i = -n) \end{aligned}$$

Therefore,

$$E(\varepsilon_i) = 0 \quad (3)$$

Now from equation (1),

$$A(x : N) = \mu + A(\varepsilon : N)$$

where

$$A(x : N) = \frac{1}{N} \sum_{i=1}^N x_i$$

$$\& A(\varepsilon : N) = \frac{1}{N} \sum_{i=1}^N \varepsilon_i$$

By law of large numbers [22, 23],

$$A(\varepsilon : N) = \frac{1}{N} \sum_{i=1}^N \varepsilon_i \text{ converges in probability to 0 as } N \rightarrow \infty \quad (4)$$

which implies,

$$A(x : N) = \frac{1}{N} \sum_{i=1}^N x_i \text{ converges in probability to } \mu \text{ as } N \rightarrow \infty \quad (5)$$

This result can also be obtained as a consequence of the law of large numbers together with the fact that

$$E(\varepsilon_i) = \mu, \text{ by equations (1) \& (3)} \quad (6)$$

Since $A(x : N) = \frac{1}{N} \sum_{i=1}^N x_i$ converges to μ as the data size $N \rightarrow \infty$,

therefore for data of finite size, the integral value nearest to $A(x : N)$ will be the value of μ i.e. the value of central tendency of the observations.

3. NUMERICAL EXAMPLE

Data on number of rainy days at New Delhi corresponding to different months during the period from 1969 to 2001 (years have been written in the table as 69, 70, 71, ..., 99, 100, 101), as shown in Table - 2, have been collected from Indian Meteorological Department

It is observed that the period June – September is the most rainy period in New Delhi compared to the other two periods October – January & February – May. Accordingly, data corresponding to these three periods, shown in Table - 3 which have

extracted from the data in Table - 2, have been considered for study.

Computational values A ($x: N$) for different values of N have been presented in Table - 4, Table - 5, Table - 6 & Table - 7 respectively.

4. FINDINGS AND CONCLUSION

It is found that the computed values in column (3) of Table - 4 shows that the trend of arithmetic mean of NoRD during the year is to converge to a value whose nearest integral value is 40. Accordingly, the central value of ANoRD during at New Delhi is 40 days.

Similarly, computed values in column (3) of Table - 5 show that the arithmetic mean of NoRD during the period June – Sept converge to a value whose nearest integral value is 30. Accordingly, the CT of NoRD at New Delhi during the period June – Sept can be regarded as 30 days.

Similarly, from the computed values in column (3) of each of the two tables namely Table - 6 & Table - 7 it is obtained that the CT of NoRD at New Delhi during the period October – January is 4 days and during the period February – May is 6 days.

It has already been shown in section 2 that $A(x : N)$ given by

$$A(x : N) = \frac{1}{N} \sum_{i=1}^N x_i$$

is to converge to a an integral value which is the central value of the observations.

However, the value of $A(x : N)$ for sample of finite size (though large) may not be an integral value. In his case, the integral value nearest to $A(x : N)$ will be central value of the observations.
